RENDA FUZHONG

IBDP Computer Science 2016-2017 Semester 1 Final Exam

Marks:

Total Marks: 75

Exam Time: 90 minutes

Please answer all the questions on the question paper.

You are not allowed to use any electronic devices.

There are two papers in this exam. You should answer ALL the questions.

Paper 1: Core, 5 MCQ + 1 Short answer question + 1 Structured question [28 marks in total]

Paper 2: Option D: OOP, 3 structured questions. [45 marks in total]

Paper 1 Core [28 marks] Please fill in your answers to MCQ 1-4 in the following table.

1	2	3	4	5

- Often the most efficient computer algorithms use a divide-and-conquer approach, for example, one in which a list is repeatedly split into two pieces until a desired outcome is reached. Which of the following use a divide-and-conquer approach?
 - I Mergesort
 - II Insertion sort
 - III Binary search
 - (A) I only
 - (B) II only
 - (C) III only
 - (D) I and III only
 - (E) I, II, and III
- Consider a sorted array arr of *n* elements, where *n* is large and *n* is even. Under which conditions will a sequential search of arr be faster than a binary search?
 - I The target is not in the list.
 - II The target is in the first position of the list.
 - III The target is in arr[1 + n/2].
 - (A) I only
 - (B) II only
 - (C) III only
 - (D) I and III only
 - (E) II and III only

When an integer is represented in base 16 (hexadecimal), the digits 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, A, B, C, D, E, F are used, where A-F represent the numbers 10-15. If base 16 is represented with the subscript hex and base 10 is represented with the subscript dec, then the decimal number 196 could be represented in hexadecimal as shown below:

$$196_{dec} = C4_{hex}$$

Which of the following is equal to 2AF_{hex}?

- (A) 27_{dec}
- (B) 300_{dec}
- (C) 687_{dec}
- (D) 4002_{dec}
- (E) 6896_{dec}
- 4 Consider the following method that will access a square matrix mat:

Suppose mat is originally

- 0 1 2 3
- 4 5 6 7
- 3 2 1 0
- 7 6 5 4

After the method call printSomething (mat) the output will be

- (A) 0 1 2 3 4 5 6 7 3 2 1 0 7 6 5 4
- (B) 0 4 5 3 2 1 7 6 5 4
- (C) 0 1 2 3 4 5 6 3 2 7
- (D) 0 4 3 7
- (E) There will be no output. An ArrayIndexOutOfBoundsException will be thrown.

5.

The following shuffling method is used to shuffle an array arr of int values. The method assumes the existence of a swap method, where swap(arr,i,j) interchanges the elements arr[i] and arr[j].

```
public static void shuffle (int[] arr)
{
    for (int k = arr.length - 1; k > 0; k--)
    {
        int randIndex = (int) (Math.random() * (k + 1));
        swap(arr, k, randIndex);
    }
}
```

Suppose the initial state of arr is 1 2 3 4 5, and when the method is executed the values generated for randIndex are 3, 2, 0, and 1, in that order. What will be the final state of arr?

- (A) 5 2 1 3 4
- (B) 1 2 5 3 4
- (C) 5 4 1 3 2
- (D) 4 5 1 3 2
- (E) 2 5 1 3 4

6. Short answer question

A sub-program <code>all_even()</code> accepts a positive integer N and outputs <code>true</code> if all digits of N are even, otherwise it outputs <code>false</code>. For example, <code>all_even(246)</code> outputs <code>true</code> and <code>all_even(256)</code> outputs <code>false</code>.

The following algorithm is constructed for the sub-program all even(N).

```
EVEN = true
loop while (N > 0) and (EVEN = true)
    if (N mod 10)mod 2 = 1 then
        EVEN = false
    end if
end loop
output EVEN
```

- (a) Explain why this algorithm does not obtain the correct result.
- (b) Outline what should be changed in the algorithm to obtain the correct result.

[2]

[3]

7. Structured Question

The table below holds student names and scores, from a class test.

NAME	SCORE
Ann Taylor	10
Boris Penn	18
Ivan Troth	8
Peter Hu	9
Mary Looty	7

(a)	Draw a diagram to show how the data given in the table could be stored in a binary tree
	in the order of scores. Data should be inserted into the binary tree in the order given in
	the table (ie data about Ann Taylor is to be inserted first).

[3]

(b) The same data could be inserted into a singly linked list in descending order of scores. Draw a diagram of this singly linked list.

[3]

[2]

[2]

- (c) Compare the data structures in part (a) and part (b) in terms of:
 - (i) searching
 - (ii) storage requirements.
- (d) Consider the following **recursive** algorithm, in which X and Y are parameters in the method F. The return statement gives the value that the method generates.

```
F(X,Y)
    if X < Y then
        return F(X+1,Y-2)
    else if X = Y
        return 2*F(X+2,Y-2)-2
    else
        return 2*X+4*Y
    end if</pre>
```

Determine the value of F(5,11).

Paper 2 Option: OOP [45 marks]

A delivery company uses trains in its operations. It uses an object-oriented program to keep track of its trains and the parcels that it carries.

The company has many objects in their program; here are some of them.

Object	Description	
Train	Each Train is made up of RollingStock objects, each of which is either a	
ITAIN	Wagon or an Engine.	
RollingStock	A RollingStock object can be an Engine (that can pull) or a Wagon (that needs to be pulled). Each RollingStock has a unique ID number and a weight.	
Engine	A variety of RollingStock. Each Engine has a maximum weight that it can pull.	
Wagon	A variety of RollingStock. Each Wagon has a maximum cargo weight.	
Parcel	Each Parcel is tagged with a tracking number, the addresses from where it came (origin) and to where it is going (destination) and its weight.	

The code on the following pages implements the Train class used in this program.

```
public class Train
  private Engine[] mEngines;
  private Wagon[] mWagons;
  private int mEngineCount;
  private int mWagonCount;
  private int mTrainNumber;
                               // Total weight in kilograms
  private double mWeight;
  public Train(int number)
    mTrainNumber = number;
    mEngines = new Engine[6]; // The train can have up to 6 engines
    mEngineCount = 0;
    mWagons = new Wagon[100]; // The train can have up to 100 wagons
    mWagonCount = 0;
    mWeight = 0;
  public void addEngine( Engine newEngine )
    mEngines[mEngineCount] = newEngine;
    mEngineCount++;
  public Engine removeEngine()
    mEngineCount--;
    return mEngines[mEngineCount];
  public void addWagon( Wagon newWagon)
    mWagons[mWagonCount] = newWagon;
    mWagonCount++;
  public Wagon removeWagon()
  {// Code to be written
  public double getWeight()
  {// Code to be written
```

```
public class RollingStock
   private int mIDNumber;
   private double mWeight;
   public RollingStock(int ID, double weight)
     mIDNumber = ID;
     mWeight = weight; // Weight is in kilograms
   // Accessor methods
   public double getWeight() { return mWeight; }
   public int getID() { return mIDNumber; }
   // Other methods
     . . .
 }
 public class Engine extends RollingStock
   private double mPullingWeight;
                                      // maximum weight engine can pull
   public Engine(int ID)
     super(ID, 120000);
                                      // Engines weigh 120000 kilograms
     mPullingWeight = 1400000;
                                      // Engines can pull 1400000 kilograms
   // Accessor methods
   public double getWeight() { return super.getWeight(); }
   // Other methods
 public class Wagon extends RollingStock
   private Parcel[] mParcels;
   private int mParcelCount;
   public Wagon(int ID)
     super(ID, 32000);
                             // Empty wagon weighs 32000 kilograms
     mParcels = new Parcel[100];
     mParcelCount = 0;
   // Accessor methods
   public int getWagonID() { return this.getID(); }
   public double getWeight()
     // Code to be written
   // Other methods
8. Structured Question
    Define the function of a constructor.
```

- [2]
- (b) Outline the advantages of polymorphism, using the RollingStock class as an example. [3]
- Construct a unified modelling language (UML) diagram of the Train class. [3]
- Construct a method getNumberOfWagons(), part of the Train class, that returns the number of wagons currently coupled to the train. [2]
- Construct the removeWagon() method that will remove one wagon from a train and return the removed object. Include appropriate error checking. [5]

8.		

8.

9. Structured Question

- (a) Outline **one** advantage of using standard library collections. [2]
- (b) Describe **two** ways in which programming by a team differs from programming by an individual working alone. [4]

The following code implements the Parcel class used in the delivery company's program.

```
public class Parcel
{
   private int trackingID;
   private double weight;
   public String destinationAddress;
   public String originAddress;
   public Parcel(int ID)
   {
      trackingID = ID;
      weight = 0;
   }
   public void setWeight(double newWeight) { weight = newWeight; }
   public double getWeight() { return weight; }
}
```

The origin and destination addresses are stored in a Parcel object as simple strings. However, addresses are complex and there are a lot of different pieces of information that may or may not be present such as a first name or a business name, in addition to house number, street name, city and country.

It has been decided to create a new Address class to handle this information.

(c) State the appropriate data type to be used in the Address class to store

- (i) the street name; [1]
- (ii) the building number; [1]
- (iii) an indication of whether or not this is a business address. [1]
- (d) Identify the changes to the Parcel class that will be needed to make use of the new Address class. [3]

Separate OriginAddress and DestinationAddress classes will be created. The destination address may contain special instructions to the delivery person. The origin address contains a variable that indicates if the parcel was collected from the customer's house or from the local post office.

(e) Outline how these **two** new classes can be created with minimal duplication of code. [3]

9.	

10. Structured Question

(a) Consider the following code fragment.

```
Train A = new Train(123);
Engine B = new Engine(7);
A.addEngine(B);
Wagon C = new Wagon(23);
A.addWagon(C);
Wagon D = new Wagon(66);
A.addWagon(D);
Wagon E = new Wagon(71);
A.addWagon(E);
A.addEngine(new Engine(9));
```

- (i) Draw the mEngines array after the code fragment has been executed. [2]
- (ii) State the value of mEngineCount after the code fragment has been executed. [1]

[2]

[2]

(iii) Draw the mwagons array after both the code fragment above **and** the code fragment below have been executed.

```
Wagon F = A.removeWagon();
F = A.removeWagon();
A.addWagon(new Wagon(214));
```

The parcels loaded into a wagon cannot weigh more than the capacity of the wagon. A train's engines must have enough combined power to pull the loaded wagons. The company needs to be able to check that these requirements are being met.

- (b) Construct the getWeight() method in the Wagon class that returns the total combined weight of the parcels currently in the wagon and the wagon itself. [4]
- (c) Construct the getWeight() method in the Train class that returns the total **combined** weight of all the parcels, engines and wagons in a train. [4]
- (d) Explain why having a getWeight() method in both the Train and Wagon classes does not cause a compiler error, even though the Train class does not inherit from the RollingStock class.

10.
